

SQL JOINS (Basic Idea)

- Joins are used to **combine data from two or more tables**
 - Tables are joined using a **common column (usually primary key & foreign key)**
-

INNER JOIN

- Returns **only matching records** from both tables
- Intersection of Table A and Table B
- If there is no match, the row is not shown

Example idea:

- Joining film and language
 - Only films that have a matching language_id are returned
-

LEFT JOIN

- Returns **all records from left table**
- Matching records from right table
- If no match, right side columns show **NULL**

Used when:

- You want all customers even if they have no rentals
-

RIGHT JOIN

- Opposite of LEFT JOIN
 - Returns **all records from right table**
 - Matching records from left table
 - If no match, left side shows NULL
-

FULL OUTER JOIN

- Returns **everything from both tables**
- Matching + non-matching rows
- If no match, NULL values appear

Note:

- MySQL does not support FULL OUTER JOIN directly
 - Achieved using:
 - LEFT JOIN
 - UNION
 - RIGHT JOIN
-

FULL JOIN using UNION

- LEFT JOIN gives all left records
- RIGHT JOIN gives all right records
- UNION combines both

- This gives full outer join result
-

SELF JOIN

- Joining a table with **itself**
- Used to compare rows within the same table

Example:

- Finding staff working in the same store
- Table is aliased as s1 and s2
- Condition:
 - same `store_id`
 - different `staff_id` (`<>`)

CROSS JOIN (Cartesian Join)

- Every row of table A joins with every row of table B
 - If A has 3 rows and B has 3 rows → result = 9 rows
 - Rarely used
 - Mostly for testing or combinations
-

EXISTS (WHERE EXISTS)

- Used to check if a subquery returns at least one row

- Returns TRUE or FALSE
- Stops checking once a match is found (efficient)

Example idea:

- Select customers who have rentals
 - EXISTS checks rental table for matching customer_id
-

JOIN vs EXISTS vs INNER JOIN

- INNER JOIN → returns actual matching rows
 - EXISTS → just checks if matching row exists
 - EXISTS is faster for checking conditions
-

Special JOIN Condition (ON 1 = 0)

- Always false condition
 - Used with UNION to force no match
 - Helps combine data from unrelated tables
 - Produces NULLs intentionally
-

Normalization in SQL

- Process of organizing data
- Reduces redundancy

- Improves data integrity
-

First Normal Form (1NF)

- Each column should contain **atomic values**
 - No multiple values in one column
 - Each cell holds only one value
 - Columns should have unique names
-

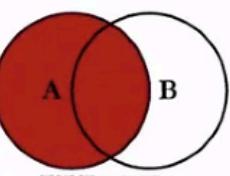

Second Normal Form (2NF)

- Table must already be in 1NF
 - No partial dependency
 - Non-key columns depend **only on the primary key**
 - Important for composite keys
-

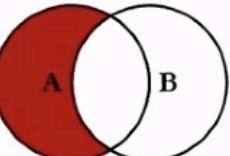

Third Normal Form (3NF)

- Table must be in 2NF
 - No transitive dependency
 - Non-key columns should not depend on other non-key columns
 - Depends only on primary key
-

SQL JOINS

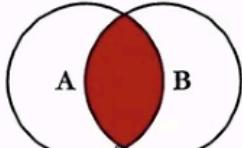

```
SELECT <select_list>
FROM TableA A
LEFT JOIN TableB B
ON A.Key = B.Key
```

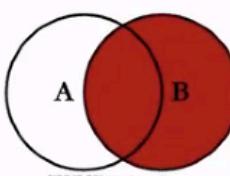

```
SELECT <select_list>
FROM TableA A
LEFT JOIN TableB B
ON A.Key = B.Key
WHERE B.Key IS NULL;
```

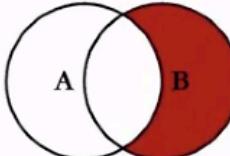

```
SELECT <select_list>
FROM TableA A
FULL OUTER JOIN TableB B
ON A.Key = B.Key
```

```
SELECT <select_list>
FROM TableA A
INNER JOIN TableB B
ON A.Key = B.Key
```

```
SELECT <select_list>
FROM TableA A
RIGHT JOIN TableB B
ON A.Key = B.Key
```

```
SELECT <select_list>
FROM TableA A
RIGHT JOIN TableB B
ON A.Key = B.Key
WHERE A.Key IS NULL;
```

```
SELECT <select_list>
FROM TableA A
FULL OUTER JOIN TableB B
ON A.Key = B.Key
WHERE A.Key IS NULL
OR B.Key IS NULL;
```
